

## Lecture 3: Context-Free Languages and Pushdown Automata

*Lecturer: Renjie Yang***3.1 Grammar**

Sample English grammar rules:

sentence  $\rightarrow$  subject predicatesubject  $\rightarrow$  article adjective nounpredicate  $\rightarrow$  verb object**Example** The big dog chased the cat.**Definition 3.1** A grammar is a 4-tuple  $(N, T, R, S)$  consists of:

- A finite set  $N$  of grammar symbols called non-terminals;
- A finite set  $T$  of symbols called terminals, such that  $N \cap T = \emptyset$ ;
- A finite set  $R$  of grammar rules of the form  $\gamma \rightarrow \delta$  where  $\gamma$  and  $\delta$  are strings over the symbol set  $N \cup T$  with the following restrictions:
  - $\gamma$  is not the empty string;
  - There is at least one production with  $S$  alone on the left hand side;
  - Each non-terminal must appear on the left hand side of some grammar rule;
- A non-terminal symbol  $S$  called start symbol.

**Example** Let  $\Sigma = \{a, b, c\}$ ,  $S$  is the start symbol. The following rules is a grammar for  $\Sigma^*$ : $S \rightarrow \epsilon$  $S \rightarrow aS$  $S \rightarrow bS$  $S \rightarrow Sc$ **Example** Languages and their corresponding grammar: $\{a^n \mid n \in \mathbb{N}\} \quad S \rightarrow aS \mid \epsilon$  $\{a^n b^n \mid n \in \mathbb{N}\} \quad S \rightarrow aSb \mid \epsilon$  $\{(ab)^n \mid n \in \mathbb{N}\} \quad S \rightarrow abS \mid \epsilon$ **Note** A grammar is called a regular grammar if each of its grammar rule takes one of the following forms where the uppercase letters are non-terminals and  $w$  is a non-empty string of terminals:

- $S \rightarrow \epsilon$
- $S \rightarrow w$
- $S \rightarrow T$

- $S \rightarrow wT$

**Note** A regular language can be written by FSM, regular expression, or regular grammar. For example,

$a^*b$

$S \rightarrow aS; S \rightarrow b$

and the following FSM

all express the same language  $\{b, ab, aab, aaab, \dots\}$

## 3.2 Context-Free Grammar

**Definition 3.2** A context-free grammar is a 4-tuple  $(V, \Sigma, R, S)$ , where

1.  $V$  is a finite set called the variables;
2.  $\Sigma$  is a finite set, disjoint from  $V$ , called the terminals;
3.  $R$  is a finite set of rules, with each rule being a variable and a string of variables and terminals;
4.  $S \in V$  is the start variable.

**Definition 3.3** If  $u, v$  and  $w$  are strings of variables and terminals, and  $A \rightarrow w$  is a rule of the grammar, we say that  $uAv$  yields  $uwv$ , written  $uAv \Rightarrow uwv$ . Say that  $u$  derives  $v$ , written  $u \xRightarrow{*} v$ , if  $u = v$  or if a sequence  $u_1, u_2, \dots, u_k$  exists for  $k \geq 0$  and

$$u \Rightarrow u_1 \Rightarrow u_2 \Rightarrow \dots \Rightarrow u_k \Rightarrow v.$$

The language of the grammar is  $\{w \in \Sigma^* \mid S \xRightarrow{*} w\}$ .

**Definition 3.4** A context-free language is a language generated by a context-free grammar.

**Example**  $S \rightarrow (S) \mid SS \mid \epsilon$

**Example**  $\{0^n 1^n \mid n \geq 0\}$ :  $S \rightarrow \epsilon \mid 0S1$

**Example**  $L = \{w \mid w \in \{0, 1\}^* \text{ and the number of 0's equals the number of 1's}\}$

$S \rightarrow 0A \mid 1B \mid \epsilon$

$A \rightarrow 1S \mid 0AA$

$B \rightarrow 0S \mid 1BB$

$S \rightarrow SAB \mid \epsilon$

$A \rightarrow 0S1 \mid \epsilon$

$B \rightarrow 1S0 \mid \epsilon$

**Definition 3.5** If a grammar generates the same string in several different ways, we say that the string is derived ambiguously in that grammar. If a grammar generates some string ambiguously, we say that the grammar is ambiguous.

**Example**  $S \rightarrow S + S | S \times S | a$

**Theorem 3.6** Every regular language is context-free.

**Proof:** Given a DFA for the regular language, we can construct a context-free grammar that generates the same language through the following steps:

- make a variable for each state;
- make the variable for the starting state the starting variable;
- make a rule for each edge;
- Add an epsilon rule for each accept state.

■

**Definition 3.7** A context-free grammar is in Chomsky normal form if every rule is of the form

$$\begin{aligned} A &\rightarrow BC \\ A &\rightarrow a \end{aligned}$$

where  $a$  is any terminal and  $A$ ,  $B$ , and  $C$  are any variables, except that  $B$  and  $C$  may not be the start variable. In addition, we permit the rule  $S \rightarrow \epsilon$ , where  $S$  is the start variable.

**Example**

$$S \rightarrow ASA | aB$$

$$A \rightarrow B | S$$

$$B \rightarrow b | \epsilon$$

**Theorem 3.8** Context-free languages are closed under union operation.

**Proof:** Let  $L_1$  and  $L_2$  be two context-free languages. We can construct a context-free grammar for the union of the two by adding a grammar rule:  $S_0 \rightarrow S_1 | S_2$ , where  $S_1$  and  $S_2$  are the start symbol for  $L_1$  and  $L_2$  respectively. ■

**Theorem 3.9** Context-free languages are closed under concatenation operation.

**Proof:** Let  $L_1$  and  $L_2$  be two context-free languages. We can construct a context-free grammar for the union of the two by adding a grammar rule:  $S_0 \rightarrow S_1 S_2$ , where  $S_1$  and  $S_2$  are the start symbol for  $L_1$  and  $L_2$  respectively. ■

**Example** A context-sensitive grammar:  $L = \{1^n 2^n 3^n \mid n \geq 1\}$

$$S \rightarrow 1SBC$$

$$S \rightarrow \epsilon$$

$$CB \rightarrow HB$$

$HB \rightarrow HC$   
 $HC \rightarrow BC$   
 $1B \rightarrow 12$   
 $2B \rightarrow 22$   
 $2C \rightarrow 23$   
 $3C \rightarrow 33$

**Note** There could be more than one different grammars for the same language.  
 $S \rightarrow aS|aaS|b$

### 3.3 Pushdown Automata

**Definition 3.10** A pushdown automaton is a 6-tuple  $(Q, \Sigma, \Gamma, \delta, q_0, F)$ , where  $Q, \Sigma, \Gamma, F$  are all finite sets:

1.  $Q$  is the set of states,
2.  $\Sigma$  is the input alphabet,
3.  $\Gamma$  is the stack alphabet,
4.  $\delta : Q \times \Sigma_\epsilon \times \Gamma_\epsilon \rightarrow \wp(Q \times \Gamma_\epsilon)$  is the transition function,
5.  $q_0 \in Q$  is the start state,
6.  $F \subset Q$  is the set of accept states.

**Definition 3.11** A pushdown automaton  $M = (Q, \Sigma, \Gamma, \delta, q_0, F)$  accepts input  $w$  if  $w$  can be written as  $w = w_1w_2 \cdots w_m$ , where each  $w_i \in \Sigma_\epsilon$  and sequences of states  $r_0, r_1, \dots, r_m \in Q$  and strings  $s_0, s_1, \dots, s_m \in \Gamma^*$  exist that satisfy the following three conditions:

1.  $r_0 = q_0$  and  $s_0 = \epsilon$ .
2. For  $i = 0, \dots, m-1$ , we have  $(r_{i+1}, b) \in \delta(r_i, w_{i+1}, a)$ , where  $s_i = at$  and  $s_{i+1} = bt$  for some  $a, b \in \Sigma_\epsilon$  and  $t$  in  $\Gamma^*$ .
3.  $r_m \in F$ .

**Example** Let  $M$  be  $(Q, \Sigma, \Gamma, \delta, q_0, F)$ , where

$Q = \{q_1, q_2, q_3, q_4\}$

$\Sigma = \{0, 1\}$

$\Gamma = \{0, \$\}$

$F = \{q_1, q_4\}$

$\delta$  is given by the following table:

| Input: | 0 |    |                | 1 |    |                       | $\epsilon$ |    |                       |
|--------|---|----|----------------|---|----|-----------------------|------------|----|-----------------------|
| Stack: | 0 | \$ | $\epsilon$     | 0 | \$ | $\epsilon$            | 0          | \$ | $\epsilon$            |
| $q_1$  |   |    |                |   |    |                       |            |    | $\{(q_2, \$)\}$       |
| $q_2$  |   |    | $\{(q_2, 0)\}$ |   |    | $\{(q_3, \epsilon)\}$ |            |    |                       |
| $q_3$  |   |    |                |   |    | $\{(q_3, \epsilon)\}$ |            |    | $\{(q_4, \epsilon)\}$ |
| $q_4$  |   |    |                |   |    |                       |            |    |                       |

The machine  $M$  can also be described by the following state diagram:

$M$  is a pushdown automaton that recognizes language  $\{0^n 1^n \mid n \geq 0\}$

**Note** The stack of a pushdown automata can be non-empty when the computation finishes.

**Example**  $aa^*bc$

**Example** All strings over  $\{a, b\}$  with the same number of  $a$ 's and  $b$ 's.

**Example**  $S \rightarrow \epsilon | aSb | aaS$

**Theorem 3.12** *If a language is context free, then some pushdown automaton recognizes it.*

**Example** Construct a pushdown automaton from the following grammar:

$$S \rightarrow aTb|b$$

$$T \rightarrow Ta|\epsilon$$
